

Babel in React

Simple idea

Babel converts modern JavaScript and JSX into plain JavaScript that browsers understand. Browsers don't understand JSX or some new JS features directly—Babel fixes that.

Why React needs Babel

When you write React, you usually write things like this:

```
jsx
const App = () => {
  return <h1>Hello World</h1>;
};
```

 Copy code

Browsers cannot understand `<h1>` inside JavaScript
So Babel converts it into something like this:

```
js
const App = () => {
  return React.createElement("h1", null, "Hello World");
};
```

 Copy code

What Babel does in React

Babel mainly:

1. Converts JSX → JavaScript
2. Converts modern JS (ES6+) → older JS (ES5)

Conclusion

Babel is an essential JavaScript compiler (transpiler) used in React to convert modern JavaScript code (like ES6+) and the special JSX syntax into a backwards-compatible version of JavaScript that all browsers and environments can understand.
